Breaking the Barrier: NMR Spectroscopy of Molecular Machines a t One Mega -Dalton and Beyond

Cells employ macromolecular assemblies, called molecular machines, to perform a myriad of biological tasks. Gaining an atomic-level understanding of the mode of operation of these machines represents the “holy grail” of structural biology. NMR spectroscopy is a powerful method for studying the structural and motional properties of proteins with molecular weights on the order of 50 kDa. However, NMR studies of molecular machines have been elusive due to their extreme masses (mega-Dalton and beyond). This lecture outlines how the TROSY (transverse relaxation optimized spectroscopy) methodology breaks this barrier and enables NMR investigations of protein systems with molecular weights approaching one mega-Dalton. Advances in NMR pulse sequences and biosynthetic production of isotopically labeled proteins will be discussed. It will be show emerging technique contributes to an understanding of the regulation of the bacterial protein degradation n
